# **Basics of molecular dynamics**

- The basic idea of molecular dynamics (MD) simulations is to calculate how a system of particles evolves in time.
  - The method was first used by Alder and Wainwright in 1957 to calculate properties of many-body systems. They called the particles *molecules*.
    - There is an interesting parallel to classical mechanics here. The two-body motion problem was solved by Newton way back then. The three-body problem was solved by a Finnish guy, Sundman, in the early part of the last century but the solution is utterly impractical (10<sup>8000000</sup> terms needed in a series expansion).
- The *N*-body problem, *N* > 3, can not be solved analytically. MD can also described to be a numerical way of solving the *N*-body problem. The solution is of course never exact, but if done properly it can be done arbitrarily accurately.
- Consider a set of atoms at positions r<sub>i</sub> and some interaction model which gives us the potential energy of the system V({r<sub>i</sub>})
- · In Newtonian mechanics we then get:

$$\frac{d\mathbf{r}_i}{dt} = \mathbf{v}_i , \qquad \frac{d}{dt}(m_i \mathbf{v}_i) = \mathbf{F}_i = -\nabla_i V = -\nabla_i \left[ \sum_j V_2(\mathbf{r}_i, \mathbf{r}_j) + \sum_{i,k} V_3(\mathbf{r}_i, \mathbf{r}_j, \mathbf{r}_k) + \dots \right]$$

• By solving the above set of equations numerically we can derive *d***r** over some short time interval *dt*.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

# Basic MD algorithm (slightly simplified)

# **General considerations**

- The above was the simplest possible example, the so called microcanonical or NVE ensemble. This means that the approach preserves the number of atoms *N*, the volume of the cell *V* and the energy *E*. Other ensembles will be dealt with later on in the course. But the NVE ensemble is the most natural one in that it is the true solution of the *N*-body problem, and corresponds to the real atom motion.
- · First MD simulations:
  - Hard spheres: B. J. Alder, T. E. Wainwright: *Phase transition for a Hard Sphere-System,* J. Chem. Phys. **27** (1957) 1208
  - Continuous potentials: J. B. Gibson, A. N. Goland, M. Milgram, G. H. Vineyard: *Dynamics of Radiation Damage*, Phys. Rev. 120 (1960) 1229.
- State-of-the-art (2008):
  - Of the order of 1 000 000 000 atoms
  - In Finland: CSC Cray XT4 (louhi.csc.fi): some 100 000 000 atoms with a realistic potential easily possible for thousands of time steps.
- If all *N* atoms interact with all atoms, one has to in principle calculate  $N^2$  interactions. This is prohibitively expensive for millions of atoms.

#### **General considerations**

- Fortunately, in practice most atomic interactions decrease rapidly in strength as r→∞. In that
  case it is enough to calculate only interactions to nearby atoms.
  - E.g. in diamond-structured semiconductors (Si, Ge, GaAs...) atoms have 4 covalent bonds, so the calculation can be reduced to 4 neighbours => 4 *N* interactions.
  - In metals atoms more than ~ 5 Å far can usually be neglected => about 80 N interactions
  - In ionic systems the interaction V ∝ 1/r, i.e. decreases very slowly. It can not be cut off, but there are smart workarounds.

#### Phase Transition for a Hard

Sphere System B. J. Alder and T. E. Wainwright University of California Radiation Laboratory, Litermore, California (Received August 12, 1957)

A CALCULATION of molecular dynamic motion has been designed principally to study the relaxations accompanying various nonequilibrium phenomena. The method consists of solving exactly (to the number of significant figures carried) the simultaneous classical equations of motion of several hundred particles by means of fast lectronic computors. Some of the details as they relate to hard spheres and to particles having square well potentials of attraction have been described.<sup>13</sup> The method has been used also to calculate equilibrium properties, particularly the equation of state of hard spheres where differences with previous Monte Carlo<sup>2</sup> results appeared.

state of hard spheres where differences with previous Monte Carlo' results appeared. The calculation treats a system of particles in a rectangular box with periodic boundary conditions.<sup>4</sup> Initially, the particles are in an ordered lattice with velocities of equal magnitude but with random orientations. After a very short initial run<sup>1,2</sup> the system reached the Maxwell-Boltzmann velocity distribution so that the pressure could thereafter be evaluated directly by means of the virial theorem, that is by the rate of change of the momentum of the colliding particles.<sup>1,3</sup> The pressure has also been evaluated from the radial distribution function.<sup>4</sup> Agreement between the two methods is within the accuracy of the calculation. A 32-particle system in a cube and initially in a facecentered cubic lattice proceeded at about 300 collisions an hour on the UNIVAC. For comparison a 96-particle system in a rectangular box and initially in a hexagonal arrangement has been calculated, however only at high densities so far. No differences in the pressures can be detected. It became apparent that some long runs were necessary at intermediate densities, accordingly the IBM-704 was utilized where, for 32 particles, an hour is required for 7000 collisions. Larger systems of 108, 256, and 500 particles can also conveniently be handled; in an hour 2000, 1000, and 500 collisions, respectively, can be calculated. The results for 256 and 500 particles are not now presented due to inadequate statistics.

#### Dynamics of Radiation Damage\*

J. B. GIBSON, A. N. GOLAND,<sup>†</sup> M. MILGRAM, AND G. H. VINEYARD Brookhaven National Laboratory, Upton, New York (Received July 14, 1960)

Radiation damage events at low and moderate energies (up to 400 ev) are studied by machine calculations in a model representing copper. Orbits of knock-on atoms are found and the resulting damaged configurations are observed to consist of interstitials and vacancies. Thresholds for producing permanently displaced atoms (i.e., interstitials) are about 25 ev in the (100) direction, 25 to 30 ev in the (110) direction, and around 85 ev in the (111) direction. Collision chains in the (100) and (110) directions are prominent; at low energies the chains focus, at higher energies they defocus. Above threshold, the chains transport matter, as well as energy, and produce an interstitial at a distance. The range of (110) chains has been studied in detail. Localized vibrational modes associated with interstitials, agitations qualitatively like thermal spikes, ring annealing processes, and a higher energy process somewhat like a displacement spike have been observed. Replacements have been found to be very numerous. The configurations of various static defects have also been studied in this model. The interstitial is found to reside in a "split" configuration, sharing a lattice site with another atom. The crowdion is found not to be stable, and Frenkel pairs are stable only beyond minimum separations, which are found to be very much dependent on orientation.

$$V(r) = V_0 e^{-\beta t}$$

cohesion: inward force on border atoms

Fig. 6. Atomic orbits produced by shot in (100) plane at 40 ev. Knock-on was at A and was directed 15° above -y axis. Large circles give initial positions of atoms in plane; small dots are initial positions in plane below. Vacancy is created at A, split interstitial at D. Run to time 99. (Run No. 12).

Introduction to atomistic simulations 2008

2. Basics of molecular dynamics

Simulation cell

- In practice in most cases the atoms are arranged in a orthogonal **simulation cell** which has a size  $S_x \times S_y \times S_z$ .
  - · It is also perfectly possible to use a simulation cell with axes than are not orthogonal.
- Problem: what should we do with the atoms at the borders.
  - 1. Nothing: "free" boundaries
  - This works fine if we want to deal with e.g. a molecule, nanocluster or nanotube in vacuum.
  - · If we want to describe a continuous medium, this does not work: the atoms are left "hanging" on the surface as if they would be on the surface.

## **Simulation cell**

- 2. Fix the boundary atoms:
  - Completely unphysical, this should be avoided if possible. Sometimes it is needed and with a fairly large "sacrificial" region next to the fixed one can be perfectly OK.
- 3. Periodic boundary conditions
- To implement this very important boundary condition two things have to be done
- 1. An atom which passes over the cell boundary comes back on the other side:

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

# Simulation cell

• In practice this can be implemented as follows (Fortran 90) (note that atomic coordinates are between  $-S_r/2$  and

 $S_x/2$ ):

```
!x : particle coordinate
!periodicx : = true periodic, false free
!xsize : MD cell size (S<sub>x</sub>)
if (periodicx) then
    if (x < -xsize/2.0) x = x + xsize
    if (x >= xsize/2.0) x = x - xsize
endif
```

- Similarly for y and z
- 2. When **distances between atoms** are calculated, the periodic boundaries have to be taken into account:
- The solid box is the simulation cell, with atoms *i*, *j*, *k* and *l*. Because of the periodic boundaries, all atoms have image atoms in the repeated cells, for instance *j*', *k*', *l*'.

- When we want to get the distance between atom *i* and *j*, which distance should we use?
- Because here  $r_{ii} > r_{ii}'$ , we use for the distance between atoms *i* and *j* the vector  $r_{ii}'$ .

## Simulation cell

• As a pseudo-algorithm (Fortran 90) in the *x* dimension:

```
if (periodicx) then
    dx = x(j) - x(i)
    if (dx > xsize/2.0) dx = dx - xsize
    if (dx <= -xsize/2.0) dx = dx + xsize
endif</pre>
```

and similarly for y and z

Example in 1D

• Note that if the maximum distance by which atoms can interact  $r_{cutoff} > xsize/2$  the atom *i* should actually interact both with atom *j* and *j'*. To prevent unphysical double interactions we need to have  $xsize > 2 r_{cutoff}$ 

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

11

## **Simulation cell**

- Thus we get a system where the simulation cell has an infinite number of image cells in all directions, and a model of an infinite system.
- However, be careful!
  - Periodicity brings an artificial interaction over the simulation cell borders.
  - For instance, a strain field arising from a point source, which is infinite, will obviously be distorted at the periodic borders. Examples:
    - A single vacancy (one missing atom) in Si: in quantum mechanical calculations at least some 200 atoms are required to get the energy reliably [Puska 1998 Phys. Rev. B]
    - And for instance a 5 nm Co cluster in Cu: about 10<sup>6</sup> atoms needed to get the strain energy reliably.
  - Upper limit for the phonon wavelength.
  - $\bullet$  To test this: simulate with different N and monitor the convergence.

# Simulation cell

- · Simulating surfaces:
  - periodic boundaries only in x- and y-directions
  - free surface:
  - the bottom either:
  - a) free: simulation of a free-standing thin foil with two surfaces
  - or b) fixed to model a bulk below:
  - very bottommost atoms fixed
  - a few atom layers above fixed layers damped with e.g. a temperature control algorithm

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

13

# **Simulation cell**

- Simulation of energetic processes:
  - In a simulation where a lot of energy is brought into the MD cell in a local region, the energy has to be scaled out from the system to model a much cooler 'heat bath' in a realistic system.
  - The energetic processes may also introduce a lot of momentum into the cell, which could cause the entire cell to move.
  - Solution: fix all boundary atoms except at the surface, and do *T* scaling in a few atom layers above these, as above.
  - Here also: watch out the finite-size effects!

## Initial conditions: creating atoms

• For cubic lattices (FCC, BCC, SC, DIA) it is easy to create the lattice. For instance FCC:

- The HCP lattice is also very common, but not orthogonal in the conventional representation.
  - Because in the HCP structure  $\mathbf{a} = \mathbf{b}$ , and because  $\cos 60^\circ = 1/2$ , the HCP lattice can be transformed into an equivalent orthogonal representation. Now the new unit cell (shaded area) corresponds to two of the conventional HCP unit cells.

Introduction to atomistic simulations 2008

2. Basics of molecular dynamics

# Initial atom velocities

- · How do we set the cell temperature to a desired value?
  - We have to generate initial atom velocities which correspond to the **Maxwell-Boltzmann** distribution (which is surprisingly well valid even in crystals):

$$\rho(v_{i\alpha}) = \left(\frac{m_i}{2\pi k_{\rm B}T}\right)^{1/2} \exp\left(-\frac{1}{2}m_i v_{i\alpha}^2 / k_{\rm B}T\right); \quad \alpha = x, y, z.$$

- · This is just a Gaussian function with suitable scaling
- We usually also want to set the total momentum of the cell to zero to prevent the entire cell from starting to move:

$$\mathbf{P} = \sum_{i=1}^{N} m_i \mathbf{v}_i$$

• So in practice all this can be achieved with the code fragment on the right:

Note: 
$$\exp\left(-\frac{v_{i\alpha}^2}{2\sigma^2}\right)$$
,  $\sigma^2 = \frac{k_{\rm B}T}{m_i}$ 

2. Basics of molecular dynamics

## Initial atom velocities

- Note the factor of 2: if the simulation is started from perfect lattice sites, or bound equilibrium positions in a molecule, half of the initial kinetic energy will be changed to potential energy after a while.
- It is also possible to get realistic initial random displacements.

• This can be derived from the Debye model: the thermal displacement in the direction of the axis *i* is a Gaussian distribution of the form

$$w(\delta_i, T) = [2\pi\sigma]^{-1/2} e^{-\delta_i^2/2\sigma^2} \text{ where}$$
  
$$\sigma = \frac{20.89}{\sqrt{3}\Theta_D} \sqrt{\frac{T}{A}} \dot{A}, \text{ where } 20.89 = \sqrt{\frac{9\hbar^2}{k_B u}} \dot{A} \sqrt{K}$$

 $\Theta_{\rm D}$  = Debye temperature of the material, A = Atomic mass

- The initial position can now be obtained with Gaussian-distributed random numbers as above.
- Note, however, that this does not account for quantum mechanical zero-point vibrations which give additional displacements near 0 K.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

### **Generating random numbers**

(This topic is dealt with in much more detail on the MC simulation course)

- Almost all kinds of simuations in physics use random numbers somewhere. As we saw above, MD simulations need them at least for initial velocity generation.
- Computer-generated random numbers are of course not truly random, but if they have been generated with a good algorithm, they start to repeat each other only after a very large (e.g. 10<sup>20</sup>) number of iterations. If the number of random numbers used in the entire simulation is much less than the repeat number, the algorithm *probably* is good enough for the application.
- Random numbers can be generated for different distributions. This means that if we generate a large number of numbers and make statistics out of them, they will eventually approach some distribution.
- The most common is of course an even distribution in an interval, another very common is Gaussian-distributed numbers:

#### **Generating random numbers**

- · Evenly distributed random numbers:
  - Many programming languages offer their own random number generator (e.g. in ANSI-C **rand()**). A good rule-of-thumb regarding these is:

Never use them for anything serious !

- The reason is simply that the language standard only specifies that the generator has to be there, not that it works sensibly. Since there are no guarantees it does (there are famous examples of the opposite) it should not be used
- Most random number generators are based on modulo-arithmetics and iteration. In the simplest possible form:

$$I_{j+1} = aI_j \pmod{m}$$

- Park and Miller 'minimal standard'-generator: a = 16807,  $m = 2^{31} 1$
- In the beginning the number  $I_0$  i.e. the **seed number** is chosen randomly.
  - This can be done e.g. by using the current system time.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

# **Generating random numbers**

- One practical implementation (Fortran90):
- The repeat interval for this routine ~ 2.1•10<sup>9</sup>
- This routine is easily good enough if for instance it is only needed for the choice of random numbers in the beginning of an MD simulation.
- In a long Monte Carlo integration where random numbers are used all the time, the repeat interval may be reached after which continued running will not improve on the results (and for instance the error estimate of the result will be calculated outright wrong).

```
real function uniformrand(seed)
    implicit none
    integer :: seed,IA,IM,IQ,IR,MASK
    real :: ran0,AM
    integer :: k
    parameter (IA=16807,IM=2147483647,AM=1.0/IM)
    parameter (IQ=127773,IR=2836,MASK=123459876)
    seed=ieor(seed,MASK)
    k=seed/IQ
    seed=IA*(seed-k*IQ)-IR*k
    if (seed < 0) seed=seed+IM
    uniformrand=AM*seed
    seed=ieor(seed,MASK)
    return
end function uniformrand</pre>
```

- More on this topic for instance from the book: Press, Teukolsky, Vetterling, Flannery: **Numerical Recipes** in C/Fortran, 2nd. ed., chapter 7.
- The book is on-line in its entirety (see http://www.nr.com/).
- But see also: "Why not use Numerical Recipes?", http://math.jpl.nasa.gov/nr/ and the reply to this: http://www.nr.com/bug-rebutt.html

#### Generating random numbers

- To generate Gaussian random velocities we need to be able to generate Gaussian-distributed random numbers.
  - How to do this is dealt with in great detail in Numerical Recipes ch. 7.2. Here we only present the most efficient accurate algorithm for this:

1° Obtain two evenly distributed random numbers  $v_1$  and  $v_2$  between -1 and 1, then calculate  $w = v_1^2 + v_2^2$ 

**2°** If  $w \ge 1$  return to step 1°

**3°** Calculate  $r = \sqrt{-2\log w}$ 

**4°** Calculate  $x = rv_1 / \sqrt{w}$  and  $y = rv_2 / \sqrt{w}$ 

**5°** Return x and on next step y

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

# Choosing the MD time step

- Depends on the integration algorithm used, but not too strongly.
- The change in the atom position in the potential used should not be too strong.
- A practical, rough rule-of-thumb: the atoms should not move more than 1/20 of the nearest-neighbour distance.
- Thermal velocity of atoms (Maxwell-Boltzmann distribution):

$$E_{\rm rms} = \frac{3}{2}k_BT = \frac{1}{2}mv^2 \implies v_{\rm rms} = \sqrt{\frac{3kT}{m}}$$

- But the distribution continues much beyond this.
- Rough estimate of the time step needed: 300 K Cu (m = 63.55 u):
- $5v_{\rm rms} = 0.017$  Å/fs
- Nearest-neighbour distance 2.55 Å =>  $\Delta t = \frac{2.55/20}{0.017}$  fs = 7.5 fs
- In practice for stability  $\Delta t \leq 4$  fs.

## Choosing the MD time step

- In pure MD there is no way to increase the time step above ~ 10 fs in atom systems at ordinary temperatures (77 K and up).
  - If we would want to simulate a process which, say, takes 1 s, we would need at least 10<sup>14</sup> time steps!
- This gives an easy way to estimate the order-of-magnitude of the upper limit for the time scale MD can handle in a given time:
  - Most realistic classical MD interatomic potentials require at least of the order of 100 flops/atom/time step.
  - Say our time step is 1 fs, and we want to simulate a 10000 atom system.
  - Hence we need 10<sup>6</sup> flops/time step. To get to 1 ns =  $10^9$  fs we would need  $10^{15}$  flops. Assuming 1 Gflop/ s processor, the simulation would thus require  $10^{15}/10^9$  seconds =  $10^6$  s i.e. about 11 days. To get to 1  $\mu$ s would require some 30 years on this processor.
- Hence we see that ordinary MD is restricted to  $\leq$  100 ns processes in practical use.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

23

# Choosing the MD step

- In ordinary equilibrium MD ∆t is usually constant throughout simulation
  - But if the maximum velocity of atoms changes a lot during the simulation, it is best to use a variable time step, which increases as the maximum velocity decreases.
  - Simulations of energetic processes:

$$\Delta t_{n+1} = \min(\frac{k_t}{v_{\max}}, \frac{E_t}{F_{\max}v_{\max}}, c_{\Delta t}\Delta t_n, t_{\max})$$

- $k_t$  maximum movement distance/time step (e.g. 0.1Å)
- $E_t$  maximum allowed energy change/time step (e.g. 300 eV)
- $c_{\Delta t}$  prevents too large sudden changes (e.g.  $c_{\Delta t} = 1.1$ )
- v<sub>max</sub> maximum atom speed in system
- $F_{\rm max}$  maximum force on any atom in system
- $t_{\rm max}$  time step once heat bath *T* has been reached
- The example values above have been found to work well for binary collisions up to 1 GeV in many materials.

# Choosing the MD step

- What happens if  $\Delta t$  is too long?
  - The energy is not conserved.
  - For instance solid copper (FCC lattice, *a* = 3.615Å, EAM potential, code parcas) NVE simulation at 300 K:
  - Hence the real criterion for selecting the time step becomes energy conservation: for every:
    - new kind of system
    - new kind of process simulated
    - new material
    - new interaction potential
  - One needs to check that energy is conserved 'well enough' by some test simulations, before starting the real production runs.

#### Introduction to atomistic simulations 2008

2. Basics of molecular dynamics

25

# **Acceleration methods**

- Speeding up MD
  - This can be achieved at least in some cases where we are interested in transitions induced by thermally activated processes, i.e. processes which follow a behaviour of the type

$$\upsilon = \upsilon_0 e^{-E_{\rm A}/k_{\rm B}T}$$

where  $\upsilon$  is the rate of the process occurring.

- System spends most of its time in local potential energy minima *B<sub>i</sub>* (basins).
- Every once in a while it gets enough kinetic energy to go over the barrier  $E_A$ : rare events.
- $\bullet$  Acceleration: increase  $\upsilon$  by increasing the probability for barrier crossing.
- Modify  $E_A$  or T (??)

t (ps)

### **Acceleration methods**

- Art Voter has presented so called Hyperdynamics [A. F. Voter, J. Chem. Phys. 106 (1997) 4665; Phys. Rev. Lett. 78 (1997) 3908]. It can in some cases speed up MD by a factor of the order of 100-1000, in others not at all.
  - In this method,  $\Delta t$  does not increase, but the potential well is made shallower so that the probability of processes with a large activation energy increases. The error which is thus formed is compensated by transition state theory (which is beyond the scope of this course).
  - The method is well suited for cases where we have to overcome a high potential energy barrier in an ordered system, e.g. vacancy and adatom diffusion. But if the energy barrier is low (e.g. interstitial migration in metals) or if we have numerous local energy minima close to each other, like in most amorphous and liquid systems, the method is useless.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

# **Acceleration methods**

- Temperature accelerated dynamics (TAD)
  - There is of course always is the Arrhenius extrapolation method: if we know that in our system there is only one single activated process occurring, and nothing else, we can simulate at higher *T* and then extrapolate the Arrhenius-like exponential  $\exp(-E_A/k_BT)$  to lower *T* to know the rate or time scale at lower *T*.
  - A smart extension to Arrhenius extrapolation is Art Voter's **TAD** method [e.g. Sorensen, *Phys. Rev. B* 62 (2000) 3658; a review of Voters methods is given in *Ann. Rev. Mater. Res.* 32 (2002) 321]
  - To understand the idea in this, let us consider a system with exactly 2 activation energies (this is just a tutorial example, the method works in principle for any number of activation energies). We want to simulate what the system does at 300 K, but the processes are so slow nothing happens there. So we will use a higher *T*, say 800 K.

### **Acceleration methods**

• Let us then assume that the Arrhenius plot of the system looks as follows:

• Now when we simulate at 800 K, event type 1 will occur much more frequently than type 2. But we want to know the behaviour at 300 K, so this is wrong. The idea in TAD is to recognize *every* transition that occurs, determine its activation energy, and then leave out the events that would not occur at the lower *T*. In our example, this means that (almost) only events of type 2 would be accepted.

Introduction to atomistic simulations 2008 2. Basics of molecular dynamics

29

# **Acceleration methods**

- In principle this is an excellent idea, but in practice one needs thousands of force evaluations to recognize a transition barrier. Hence the difference between the rates of occurrance needs to be very large for a significant gain to be achieved. But the gain can be huge (Example: simulating growth of Cu (001) surface at 77 K the speedup factor is 10<sup>7</sup> !)
- Like hyperdynamics, if there are lots of shallow minima TAD tends to get stuck and never really gets anywhere.
- TAD is developed rapidly towards wider applicability, so it will be interesting to follow the progress.
