OUTLINE

We follow chapters 1-5, 7 in Galí's excellent book:

- Introduction
- Monetary Policy in Classical Model
- The Basic New Keynesian Model
- Monetary Policy Design in the Basic New Keynesian Model
- S Time-Consistency in Monetary Policy: Discretion vs. Commitment
- Monetary Policy in Open Economy

Note: many of the slides are reproduced from Galí's book's slide collection

11 Feb 2010 4 / 57

MOTIVATION

- Monetary policy has been a central area of macroeconomic research
- The macroeconomics of monetary policy studies the interaction between monetary policy, inflation and business cycles (fluctuations in economic activity)
- The modern models of monetary policy build on as most of the recent macroeconomic research on real business cycle models by Kydland and Prescott (1982) and Prescott (1986).

イロト イヨト イヨト 一日

REAL BUSINESS CYCLE REVOLUTION

METHODOLOGICAL REVOLUTION

Intertemporally optimizing agents. Budget and technology constraints.

CONCEPTUAL REVOLUTION

- In a frictionless markets under perfect competition business cycles are efficient: no need for stabilization; stabilization may be counter-productive.
- Economic fluctuations are caused by technology shocks: they are the main source of fluctuation.
- Monetary factors (price level) has a limited (or no) role: money (price level) has no effect on the real economy, real wages, relative prices, consumption, investments, employment,

nac

-INTRODUCTION

LNEW KEYNESIAN MODEL

NEW KEYNESIAN MODEL

- Methodologically similar to RBC models.
- Builds on the following features:
 - monopolistic competition
 - nominal rigidities
 - $\rightarrow\,$ short-run non-neutrality of money: real interest rate affect money supply.
- Leads to differences w.r.t RBC models: economy's response to shocks is generally inefficient.
- Removing the effects of non-neutrality is potentially welfare improving
 → role for monetary policy.

San

-INTRODUCTION

New Keynesian Model

EMPIRICAL EVIDENCE

SUPPORTIVE TO PRICE RIGIDITY

4–6 quarters by Bils and Klenow (2004), 8–11 quarters by Nakamura and Steinsson (2008), 8-11 by Dhyne et al. (2006). Wages are also rigid: 1 year, downward rigidity by Dickens et al. (2007)

NON-NEUTRALITY HARD TO MEASURE

The expected inflation does not move as nominal interest rates, when latter is changed, the real interest rate changes and, as a result, equilibrium output and employment.

This is hard to show empirically. Christiano et al. (2005) provides example.

- Equilibrium
- Monetary Policy Rules
- Motivation of money
- Motivation of money: MIUF
- Optimal policy

THE BASIC NEW KEYNESIAN MODEL

MONETARY POLICY IN CLASSICAL MODEL

L HOUSEHOLDS

HOUSEHOLD PROBLEM

Households

- Decide how much they consume, C_t , in each period and
- how much they work, N_t .
- They know the current and historical values of nominal wages W_t,
- and their savings in bonds B_t , with bond price Q_t , and
- their lump-sum taxes, T_t .
- Price level is P_t .

They cannot accumulate infinite debt (transversality condition):

$$\lim_{T\to\infty}E_tB_T\geq 0$$

イロト イポト イヨト イヨト 二日

MONETARY POLICY IN CLASSICAL MODEL

L_{HOUSEHOLDS}

Households maximize the expected present value of utility

$$\max_{\{C_t,N_t\}} \mathsf{E}_0 \sum_{t=0}^{\infty} U(C_t, N_t)$$

subject to the following (flow) budget constraint

$$P_t C_t + Q_t B_t \le B_{t-1} + W_t N_t - T_t.$$
(3.1)

MONETARY POLICY IN CLASSICAL MODEL

L_{HOUSEHOLDS}

FIRST ORDER CONDITIONS

$$\frac{U_{N,t}}{U_{C,t}} = \frac{W_t}{P_t}$$

Marginal rate of substitution between consumption and leisure (equaling real wages).

$$Q_t = \beta \mathsf{E}_t \left(\frac{U_{C,t+1}}{U_{C,t}} \frac{P_t}{P_{t+1}} \right)$$

Intertemporal marginal rate of substitution in nominal terms.

MONETARY POLICY IN CLASSICAL MODEL

SIDESTEP: LOG-LINEARIZATION

SIDESTEP TO LOG-LINEARIZATIONS

TAYLOR APPROXIMATIONS ARE ACCURATE ONLY IN THE NEIGHBORHOOD OF A POINT

As a consequence (loosely speaking) an economic model has to be stationary. This means that very often we need to stationarize the model first, ie to express it in terms of stationary variables.

Suppose we have

$$f(X_t, Y_t) = g(Z_t), \qquad (3.4)$$

with strictly positive X, Y, Z (ie the linearization point). The steady state counterpart is f(X, Y) = g(Z).

This simple summarization is, for example, in the slides by Jürg Adamek). (http://www.vwl.unibe.ch/studies/3076_e/linearisation_slides.pdf)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

MONETARY POLICY IN CLASSICAL MODEL

SIDESTEP: LOG-LINEARIZATION

Let's denote $x_t = \log(X_t)$ (for any variable). Start from replacing $X_t = \exp(\log(X_t))$ in (3.4),

$$f\left(e^{\log(X_t)}, e^{\log(Y_t)}\right) = g\left(e^{\log(Z_t)}\right)$$
 ,

Taking first-order Taylor approximations from both sides:

$$f(X, Y) + f'_{1}(X, Y)X(x_{t} - x) + f'_{2}(X, Y)Y(y_{t} - y)$$

= $g(Z) + g'(Z)Z(z_{t} - z)$ (3.5)

Often we denote $\hat{x}_t \equiv x_t - x$.

(ロ) (同) (三) (三) (三) (0,0)

MONETARY POLICY IN CLASSICAL MODEL

SIDESTEP: LOG-LINEARIZATION

Log-linearization of (3.3) around non-zero inflation and growth

In a growing economy $C_{t+1} > C_t$ and in a non-zero-inflation economy $P_{t+1} > P_t$. Hence, neither C nor P is a point. The growth rates are, however, stationary. Let's denote $\dot{X}_t \equiv X_t/X_{t-1}$. Then (3.3) is

$$Q_t = \beta \mathsf{E}_t \left(\dot{C}_{t+1}^{-\sigma} \dot{P}_{t+1}^{-1}
ight).$$

In the steady state: $Q = \beta \dot{C}^{-\sigma} / \dot{P}$. Denote $\rho \equiv -\log \beta$, then $\rho = -q - (\sigma \Delta c + \pi)$, where $\pi_t \equiv \dot{P}_t$ and $\Delta x_t \equiv \dot{x}_t$. Note also that $i_t = -q_t$.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ◆

MONETARY POLICY IN CLASSICAL MODEL

SIDESTEP: LOG-LINEARIZATION

Apply mechanically (3.5)

$$Q + Q(q_t - q) = \underbrace{\beta \dot{C}^{-\sigma} / \dot{P}}_{=Q} - \sigma \underbrace{\beta \frac{\dot{C}^{-\sigma}}{\dot{P}}}_{=Q} \frac{1}{\dot{C}} \dot{C} (\Delta \mathsf{E}_t c_{t+1} - \Delta c) + (-1) \underbrace{\beta \frac{\dot{C}^{-\sigma}}{\dot{P}}}_{=Q} \frac{1}{\dot{P}} \dot{P} (\mathsf{E}_t \pi_{t+1} - \pi).$$

and divide by Q and get rid of constants to obtain

$$q_t - q = -\sigma(\mathsf{E}_t \,\Delta c_{t+1} - \Delta c) - (\mathsf{E}_t \,\pi_{t+1} - \pi)$$

and combine with log of steady-state to obtain

$$i_t - \mathsf{E}_t \,\pi_{t+1} - \rho = \sigma \,\mathsf{E}_t \,\Delta c_{t+1} \tag{3.6}$$

MONETARY POLICY IN CLASSICAL MODEL

L_{FIRMS}

FIRMS

Firms use only labour N to produce output Y:

$$Y_t = A_t N_t^{1-\alpha}. aga{3.9}$$

Log-linearized as $y_t = a_t + (1 - \alpha)n_t$. A_t is exogenously given stationary process (a shock). Firms maximize profits

 $P_t Y_t - W_t N_t$

subject to production function (3.9) and obtain the following FOC:

$$(1-\alpha)A_t N_t^{-\alpha} = \frac{W_t}{P_t}.$$
(3.10)

which gives labour demand schedule and tells us how much labour the firm is willing to hire for given real wages and technological process A_t , $= -\infty$

MONETARY POLICY, INFLATION AND THE BU

・ロト ・日下・ ・ ヨト・

MONETARY POLICY IN CLASSICAL MODEL

L_{EQUILIBRIUM}

A CLOSER LOOK AT EMPLOYMENT RESPONSE

Let's rewrite (3.2) as follows

$$N_t^{\varphi} = \frac{W_t}{P_t} C_t^{-\sigma}$$

The elasticity of substitution is unity (or $1/\varphi$), and wealth elasticity is $-\sigma$ (or $-\sigma/\varphi$).

- \bullet The substitution effect dominates the negative wealth effect if $\sigma < 1$ and
- vice versa if $\sigma > 1$.
- They cancel each other when $\sigma = 1$ (logarithmic utility).

200

イロト イポト イヨト イヨト 二日

MONETARY POLICY IN CLASSICAL MODEL

EQUILIBRIUM

TECHNOLOGY PROCESS DEFINES PROPERTIES OF REAL INTEREST RATE

 r_t will go down if $E_t a_{t+1} < a_t$ and go up if $E_t a_{t+1} < a_t$ (like in the growing economy).

SUMMARY OF EQUILIBRIUM

In equilibrium, output, consumption, employment, real wages and real rate of return are function of productivity shock only — not of anything else! Hence monetary factors play no role in real economy, ie monetary policy is neutral w.r.t. real variables.

MONETARY POLICY IN CLASSICAL MODEL

MONETARY POLICY RULES

- Real variables are independent of monetary policy.
- Monetary policy has an important impact on nominal variables. •
- No monetary policy rule is better that any other.
- The non-existence of the interaction between nominal and real variables is in contrast to empirical evidence.

イロト イヨト イヨト

MONETARY POLICY IN CLASSICAL MODEL

MOTIVATION OF MONEY

VARIOUS APPROACHES TO MOTIVATE MONEY

In the above classical models, money had a role of unit of account: *cashless economy, cashless limit.*

Money provides liquidity services. They can be modelled, for example, as

- Real balances generate utility: Money-in-the-utility-function (MIUF)
- The transaction cost approach
 - Explicit microfounded matching models starting from double coincidence of wants
 - Cash-in-advance (CIA) constraint

We study MIUF and leave CIA as an exercise. First item can be found from micro courses.

MONETARY POLICY IN CLASSICAL MODEL

OPTIMAL POLICY

OPTIMAL MONETARY POLICY IN A CLASSICAL SETTING

Assume a hypothetical social planner that maximize the utility of representative household, that contains real money.

Social planner faces a static problem, since only an individual household (not the society as a whole) can smooth its consumption over time. The planner's problem is to maximize

$$\max U(C_t, \frac{M_t}{C_t}, N_t)$$

subject to resource constraint

$$C_t = A_t N_t^{1-\alpha}$$

イロト イポト イヨト イヨト 二日

MONETARY POLICY IN CLASSICAL MODEL

OPTIMAL POLICY

The optimality conditions are given by

$$-\frac{U_{n,t}}{U_{c,t}} = (1-\alpha)A_t N_t^{-\alpha}$$
(3.13)

$$U_{m,t} = 0$$
 (3.14)

- (3.13) First corresponds the labour market equilibrium that is independent of monetary policy (except in the non-separable MIUF case)
- (3.14) Second condition equates marginal utility of real balances to the "social"marginal cost of producing them (zero!).

From household's problem we know

$$\frac{U_{m,t}}{U_{c,t}}=1-e^{-i_t}.$$

RHS can be zero only if $i_t = 0$. This is called Friedman rule. (In steady-state) this results $\pi = -\rho(\equiv -\log(\beta)) < 0$, ie in the steady state, the price level declines at the rate of time preference.

MONETARY POLICY IN CLASSICAL MODEL

CPTIMAL POLICY

Implementation

$$i_t = \phi \ (r_{t-1} + \pi_t)$$

for some $\phi > 1$. Combined with the definition of the real rate:

$$E_t\{i_{t+1}\} = \phi \ i_t$$

whose only stationary solution is $i_t = 0$ for all t. Implied equilibrium inflation:

$$\pi_t = -r_{t-1}$$

THE BASIC NEW KEYNESIAN MODEL

L_{PRELIMINARIES}

CES AGGREGATOR

In modern macro models with imperfect competition, the Dixit-Stiglitz, or Constant-Elasticity-of-Substitution aggregator plays an important role. Consider a static optimization problem of a firm that buy infinite number of intermediate products C(i), puts them together using technology

$$C = \left[\int_0^1 C(i)^{\frac{e-1}{e}} di\right]^{\frac{e}{1-e}},$$
(4.1)

where ϵ is the elasticity of substitution (and also the price elasticity of the demand function). Its optimization problem is

$$\max_{C(i)} C \cdot P - \int_0^1 C(i) P(i) di$$

subject to the production technology (4.1).

イロト イヨト イヨト 一日

THE BASIC NEW KEYNESIAN MODEL

L_{PRELIMINARIES}

The optimality conditions is given by

$$C(i) = \left[\frac{P(i)}{P}\right]^{-\epsilon} C \quad \forall i \in [0, 1].$$

This is also the demand function of a good C(i). (You must work out the details by yourself.) Plug this to the profits and use zero profit constraint to get the aggregate price level (=price index=marginal costs):

$$P = \left[\int_0^1 P(i)^{1-\epsilon}\right]^{\frac{1}{1-\epsilon}}.$$
(4.2)

THE BASIC NEW KEYNESIAN MODEL

LINTRODUCTION

INTRODUCTION

The basic new Keynesian model consists of two key ingredients:

IMPERFECT COMPETITION

We assume that there is a continuum of firms and each produce a differentiated intermediate good for which it sets the price.

PRICE RIGIDITIES

We assume (a la Calvo (1983)) that, in each period, only a fraction of firms can change their price.

MONETARY POLICY, INFLATION AND THE BUSINESS CYCLE THE BASIC NEW KEYNESIAN MODEL

L HOUSEHOLDS

HOUSEHOLDS

Household problem is the same as in the case of classical model except that the aggregate consumption consists of continuum of goods:

$$C_t = \left[\int_0^1 C_t(i)^{\frac{e-1}{e}} di\right]^{\frac{e}{1-e}}$$

Household must allocate its consumption to different goods according to their relative price

$$C_t(i) = \left[\frac{P_t(i)}{P_t}\right]^{-\epsilon} C_t, \qquad (4.3)$$

where the aggregate price index is as in (4.2).

イロト イボト イモト 一日

L_{HOUSEHOLDS}

The optimality condition are, of course, the same and assuming same functional form of utility function, and loglinearizing, we obtain

$$w_t - p_t = \sigma c_t + \varphi n_t \tag{4.4}$$

$$c_t = \mathsf{E}_t \, c_{t+1} - \frac{1}{\sigma} (i_t - \mathsf{E}_t \, \pi_{t+1} - \rho) \tag{4.5}$$

$$m_t - p_t = y_t - \eta i_t. \tag{4.6}$$

MONETARY POLICY, INFLATION AND THE BUSINESS CYCLE	
THE BASIC NEW KEYNESIAN MODEL	
Firms	

FIRMS

Assume continuum of identical firms indexed by $i \in [0, 1]$ that use the following common production technology

$$Y_t(i) = A_t N_t(i)^{1-\alpha}.$$

All firms face an identical demand curve (4.3) and take aggregate price index P_t and aggregate consumption index C_t as given.

THE BASIC NEW KEYNESIAN MODEL

└─_{FIRMS}

CALVO FAIRY

- A firm may change price of its product only when Calvo Fairy visits.
- The probability of a visit is 1θ .
- It is independent of the length of the time and the time elapsed since the last adjustment. Hence, in each period the 1θ share of firms may change their price and rest, θ , keep their price unchanged.
- Mathematically, Calvo Fairy's visits follows Bernoulli process (discrete version of Poisson process).
- The probability distribution of the number of periods between the visits of Calvo Fairy is geometric distribution.
- The expected value of geometric distribution and, hence, the average number of periods between the price changes (of a firm) is

$$\frac{1}{1- heta}.$$

FIRMS

OPTIMAL PRICE SETTING

Let P_t^* denote the price level of the firm that receives price change signal. This is the price level of the firm that Calvo Fairy visits.

When making its pricing decision, the firm takes into account that it can change is price with the probability $1 - \theta$, ie the chosen price remains the same with probability θ .

$$\max_{P_t^{\star}} E_t \sum_{k=0}^{\infty} \theta^k Q_{t,t+k} \left\{ P_t^{\star} Y_{t+k}(P_t^{\star}) - \Psi_{t+k} \left[Y_{t+k}(P_t^{\star}) \right] \right\},$$

where $\Psi_{t+k}[Y_{t+k}(P_t^*)]$ is firm's total costs that depends on the demand function $Y_{t+k}(P_t^*)$ with a relative price of P_t^*/P_{t+k} .

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ◆

THE BASIC NEW KEYNESIAN MODEL

└─_{FIRMS}

and

$$Y_{t+k}(P_t^{\star}) = \left(\frac{P_t^{\star}}{P_{t+k}}\right)^{-\epsilon} C_{t+k}$$

The first one is the demand function that the firm faces and is due to the households' consumption index.

$$Q_{t,t+k} \equiv \beta^k \left(\frac{C_{t+k}}{C_t}\right)^{-\sigma} \left(\frac{P_t}{P_{t+k}}\right).$$

The second equation is the nominal *stochastic discount factor* (pricing kernel), that household use to price any financial asset. Note, that in our standard household's optimisation problem, the household price one-period bond using the very same pricing kernel.

イロト イポト イヨト イヨト 二日

AGGREGATE PRICE LEVEL

Note that all those firms that may set their price level (ie where Calvo Fairy visits) will choose identical price P_t^* . Let $S(t) \subset [0, 1]$ represent the set of firms that do not reoptimize their price in period t. Note that "the distribution of prices among firms not adjusting in period t corresponds to the distribution effective prices in period t - 1, though with total mass reduced to θ ". Remember the aggregate price index P_t in eq (4.2). The aggregate price level has to follow this functional form

$$P_{t} = \left[\int_{S(t)} P_{t}(i)^{1-\epsilon} di + (1-\theta) (P_{t}^{\star})^{1-\epsilon} \right]^{\frac{1}{1-\epsilon}} = \left[\theta P_{t-1}^{1-\epsilon} + (1-\theta) (P_{t}^{\star})^{1-\epsilon} \right]^{\frac{1}{1-\epsilon}}.$$
 (4.7)

FIRMS

LOG-LINEARIZATION OF AGGREGATE PRICE LEVEL

Stationarize equation (4.7), ie express it in inflation rates and in relative prices: Divide (4.7) by P_{t-1} and rise it power $1 - \epsilon$:

$$\Pi_t^{1-\epsilon} = \theta + (1-\theta) \left(\frac{P_t^{\star}}{P_{t-1}}\right)^{1-\epsilon},$$

where $\Pi_t = P_t/P_{t-1}$. Log-linearizing it around $\Pi = 1$ and $P_t^*/P_t = 1$ (zero steady state inflation, unit relative prices in steady-state):

$$\pi_t = (1-\theta)(p_t^{\star} - p_{t-1}).$$

THE BASIC NEW KEYNESIAN MODEL

MONETARY POLICY IN A NEW KEYNESIAN MODEL

ANALYTICAL SOLUTION: UNDETERMINED COEFFICIENTS

- Guess that the solution takes the form $\tilde{y}_t = \psi_{yv}v_t$ and $\pi_t = \psi_{\pi v}v_t$ (why?)
- Substitute (11) into (10),
- So Let's assume that $\hat{r}_t^n \equiv r_t^n \rho = 0$ (because it is not affected by monetary policy shocks,
- Impose these to (9) and (10) (note that $E_t v_{t+1} = \rho_v v_t$) and
- **6** solve the unknown ψ_{yy} and $\psi_{\pi y}$ to obtain

$$ilde{y}_t = -(1-eta
ho_v)\Lambda_v v_t$$

 $\pi_t = -\kappa\Lambda_v v_t$,

where $\Lambda_{\mathbf{v}} = \{(1 - \beta \rho_{\mathbf{v}})[\sigma(1 - \rho_{\mathbf{v}})\mathbf{0}\phi_{\mathbf{y}}] + \kappa(\phi_{\pi} - \rho_{\mathbf{v}})\}^{-1}$

San

THE BASIC NEW KEYNESIAN MODEL

MONETARY POLICY IN A NEW KEYNESIAN MODEL

ANALYTICAL SOLUTION: UNDETERMINED COEFFICIENTS...

• Note, however, that $v_t = \rho_v v_{t-1} + \varepsilon_t^v = \frac{1}{1 - \rho_v L} \varepsilon_t^v$, where *L* is lag-operator (or backshift operator), ie $Lx_t = x_{t-1}$.

Then, the solution ('VAR' representation) is

$$\begin{split} \tilde{y}_t &= \rho_v \tilde{y}_{t-1} - (1 - \beta \rho_v) \Lambda_v \varepsilon_t^v \\ \pi_t &= \rho_v \pi_{t-1} - \kappa \Lambda_v \varepsilon_t^v. \end{split}$$

Note, that the persistence (lagged endogenous variable) is *inherited* from the shock process v_t .

L THE BASIC NEW KEYNESIAN MODEL

MONETARY POLICY IN A NEW KEYNESIAN MODEL

Equilibrium under an Exogenous Money Growth Process

$$\Delta m_t = \rho_m \,\,\Delta m_{t-1} + \varepsilon_t^m \tag{13}$$

Money market clearing

$$\widehat{l}_t = \widehat{y}_t - \eta \, \widehat{i}_t \tag{14}$$

$$= \widetilde{y}_t + \widehat{y}_t^n - \eta \ \widehat{i}_t \tag{15}$$

where $l_t \equiv m_t - p_t$ denotes (log) real money balances.

Substituting (14) into (10):

$$(1+\sigma\eta) \quad \widetilde{y}_t = \sigma\eta \ E_t\{\widetilde{y}_{t+1}\} + \widehat{l}_t + \eta \ E_t\{\pi_{t+1}\} + \eta \ \widehat{r}_t^n - \widehat{y}_t^n \qquad (16)$$

Furthermore, we have

$$\widehat{l}_{t-1} = \widehat{l}_t + \pi_t - \Delta m_t \tag{17}$$

The Efficient Allocation

$$\max U\left(C_{t}, N_{t}\right)$$
where $C_{t} \equiv \left[\int_{0}^{1} C_{t}(i)^{1-\frac{1}{\epsilon}} di\right]^{\frac{\epsilon}{\epsilon-1}}$ subject to:
 $C_{t}(i) = A_{t} N_{t}(i)^{1-\alpha}, \ all \ i \in [0, 1]$

$$N_{t} = \int_{0}^{1} N_{t}(i) \ di$$

Optimality conditions:

$$\begin{split} C_t(i) &= C_t, \ all \ i \in [0,1] \\ N_t(i) &= N_t, \ all \ i \in [0,1] \\ - \frac{U_{n,t}}{U_{c,t}} &= MPN_t \end{split}$$

where $MPN_t \equiv (1 - \alpha) A_t N_t^{-\alpha}$.

11 Feb 2010 53 / 57

▲□▶ ▲□▶ ▲目▶ ▲目▶ 三日 - のへで

Sources of Suboptimality of Equilibrium

- 1. Distortions unrelated to nominal rigidities:
 - Monopolistic competition: $P_t = \mathcal{M} \frac{W_t}{MPN_t}$, where $\mathcal{M} \equiv \frac{\varepsilon}{\varepsilon 1} > 1$

$$\implies \quad -\frac{U_{n,t}}{U_{c,t}} = \frac{W_t}{P_t} = \frac{MPN_t}{\mathcal{M}} < MPN_t$$

Solution: employment subsidy τ . Under flexible prices, $P_t = \mathcal{M} \frac{(1-\tau)W_t}{MPN_t}$.

$$\implies -\frac{U_{n,t}}{U_{c,t}} = \frac{W_t}{P_t} = \frac{MPN_t}{\mathcal{M}(1-\tau)}$$

Optimal subsidy: $\mathcal{M}(1-\tau) = 1$ or, equivalently, $\tau = \frac{1}{\varepsilon}$.

• *Transactions friction* (economy with valued money): assumed to be negligible

11 Feb 2010 53 / 57

・ロト ・ 回 ト ・ 三 ト ・ 三 ・ つへつ

2. Distortions associated with the presence of nominal rigidities:

• Markup variations resulting from sticky prices: $\mathcal{M}_t = \frac{P_t}{(1-\tau)(W_t/MPN_t)} = \frac{P_t\mathcal{M}}{W_t/MPN_t}$ (assuming optimal subsidy)

$$\implies -\frac{U_{n,t}}{U_{c,t}} = \frac{W_t}{P_t} = MPN_t \frac{\mathcal{M}}{\mathcal{M}_t} \neq MPN_t$$

Optimality requires that the average markup be stabilized at its frictionless level.

• Relative price distortions resulting from staggered price setting: $C_t(i) \neq C_t(j)$ if $P_t(i) \neq P_t(j)$. Optimal policy requires that prices and quantities (and hence marginal costs) are equalized across goods. Accordingly, markups should be identical across firms/goods at all times.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ・三 ・ つへつ

Optimal Monetary Policy in the Basic NK Model

Assumptions:

 \bullet optimal employment subsidy

 \Longrightarrow flexible price equilibrium allocation is efficient

 \bullet no inherited relative price distortions, i.e. $P_{-1}(i)=P_{-1}$ for all $i\in[0,1]$

 \implies the efficient allocation can be attained by a policy that stabilizes marginal costs at a level consistent with firms' desired markup, *given existing prices*:

- no firm has an incentive to adjust its price, i.e. $P_t^* = P_{t-1}$ and, hence, $P_t = P_{t-1}$ for $t = 0, 1, 2, \dots$ As a result the aggregate price level is fully stabilized and no relative price distortions emerge.
- equilibrium output and employment match their counterparts in the (undistorted) flexible price equilibrium allocation.

Equilibrium under the Optimal Policy

$$\widetilde{y}_t = 0$$
$$\pi_t = 0$$
$$i_t = r_t^n$$

for all t.

Implementation: Some Candidate Interest Rate Rules

Non-Policy Block:

$$\widetilde{y}_{t} = -\frac{1}{\sigma} (i_{t} - E_{t} \{ \pi_{t+1} \} - r_{t}^{n}) + E_{t} \{ \widetilde{y}_{t+1} \}$$
$$\pi_{t} = \beta \ E_{t} \{ \pi_{t+1} \} + \kappa \ \widetilde{y}_{t}$$

ANTTI RIPATTI (BOF)

MONETARY POLICY, INFLATION AND THE BU

11 Feb 2010 53 / 57

◆□▶ ◆□▶ ◆ 三▶ ◆ 三▶ ・ 三 ・ つへぐ

An Exogenous Interest Rate Rule

$$i_t = r_t^n$$

Equilibrium dynamics:

$$\begin{bmatrix} \widetilde{y}_t \\ \pi_t \end{bmatrix} = \mathbf{A_0} \begin{bmatrix} E_t \{ \widetilde{y}_{t+1} \} \\ E_t \{ \pi_{t+1} \} \end{bmatrix}$$

where

$$\mathbf{A}_{\mathbf{O}} \equiv \begin{bmatrix} 1 & \frac{1}{\sigma} \\ \kappa & \beta + \frac{\kappa}{\sigma} \end{bmatrix}$$

Shortcoming: the solution $\tilde{y}_t = \pi_t = 0$ for all t is not unique: one eigenvalue of $\mathbf{A}_{\mathbf{O}}$ is strictly greater than one.

 \rightarrow indeterminacy. (real and nominal).

Shortcomings of Optimal Rules

- they assume observability of the natural rate of interest (in real time).
- this requires, in turn, knowledge of:
 - (i) the true model
 - (ii) true parameter values
 - (iii) realized shocks

Alternative: "simple rules" , i.e. rules that meet the following criteria:

- the policy instrument depends on observable variables only,
- do not require knowledge of the true parameter values
- \bullet ideally, they approximate optimal rule across different models

San

イロト イヨト イヨト 一日

Simple Monetary Policy Rules

Welfare-based evaluation:

$$\mathbb{W} \equiv -E_0 \sum_{t=0}^{\infty} \beta^t \left(\frac{U_t - U_t^n}{U_c C} \right) = \frac{1}{2\lambda} E_0 \sum_{t=0}^{\infty} \beta^t \left(\kappa \ \tilde{y}_t^2 + \epsilon \ \pi_t^2 \right)$$

 \Rightarrow expected average welfare loss per period:

$$\mathbb{L} = \frac{1}{2\lambda} \left[\kappa \ var(\widetilde{y}_t) + \epsilon \ var(\pi_t) \right]$$

See Appendix for Derivation.

200

イロト イヨト イヨト 一日

A Taylor Rule

$$i_t = \rho + \phi_\pi \ \pi_t + \phi_y \ \widehat{y}_t$$

Equivalently:

$$i_t = \rho + \phi_\pi \ \pi_t + \phi_y \ \widetilde{y}_t + v_t$$

where $v_t \equiv \phi_y \ \hat{y}_t^n$

Equilibrium dynamics:

$$\begin{bmatrix} \widetilde{y}_t \\ \pi_t \end{bmatrix} = \mathbf{A}_T \begin{bmatrix} E_t \{ \widetilde{y}_{t+1} \} \\ E_t \{ \pi_{t+1} \} \end{bmatrix} + \mathbf{B}_T \left(\widehat{r}_t^n - \phi_y \ \widehat{y}_t^n \right)$$

where

$$\mathbf{A}_T \equiv \Omega \begin{bmatrix} \sigma & 1 - \beta \phi_{\pi} \\ \sigma \kappa & \kappa + \beta (\sigma + \phi_y) \end{bmatrix} ; \quad \mathbf{B}_T \equiv \Omega \begin{bmatrix} 1 \\ \kappa \end{bmatrix}$$

and $\Omega \equiv \frac{1}{\sigma + \phi_y + \kappa \phi_\pi}$. Note that $\hat{r}_t^n - \phi_y \ \hat{y}_t^n = -\psi_{ya}^n \left[\sigma(1 - \rho_a) + \phi_y\right] a_t$ Exercise: $\Delta a_t \sim AR(1)$ + modified Taylor rule $i_t = \rho + \phi_\pi \ \pi_t + \phi_y \ \Delta y_t$
